

A comparison of perioperative pressure measurements in the aneurysm sac and parent artery in ruptured and unruptured aneurysm

Porovnání perioperačního měření tlaku ve vaku aneuryzmatu a v mateřské tepně u prasklých a neprasklých aneuryzmat

Abstract

Aim: The purpose of this study is to compare the pressure differences between the aneurysm sac and the parent artery in both ruptured and unruptured aneurysms to investigate the effect of pressure differences on the aneurysm rupture. **Material and methods:** Patients treated for ruptured and unruptured aneurysms were included in the study. All the cases were imaged using catheter angiography and the aneurysms were filled with coils. The measurement was made just before and after the microcatheter was advanced into the aneurysm. The aneurysm's height-width, maximum dome diameter, neck diameter and entrance angle were measured in three-dimensional images. **Results:** Endovascular treatment of 40 aneurysms was performed. Of these aneurysms, 17 (42.5%) were unruptured; 23 (57.5%) were ruptured. There was no statistically significant difference between patient groups with ruptured and unruptured aneurysms in terms of the demographic data and risk factors, the perioperative pressure measurements in the aneurysm sac and parent artery and the aneurysm morphological measurement. **Conclusion:** In our study, perioperative pressure measurements in the aneurysm sac and parent artery were similar in both ruptured and unruptured aneurysms, and no statistically significant difference was found in any result between the groups. A wider series of studies about aneurysm's characteristics such as shape or wall properties will contribute to our knowledge to clarify the mechanisms that play a role in the formation, growth and rupture of intracranial aneurysms.

Abstrakt

Cíl: Cílem studie je porovnat rozdíly tlaku ve vaku aneuryzmatu a v mateřské tepně (u prasklých i neprasklých aneuryzmat) a vyhodnotit vliv rozdílů tlaku na rupturu aneuryzmatu. **Materiál a metody:** Do studie byli zahrnuti pacienti s rupturou i bez ruptury aneuryzmatu. Ve všech případech byla provedena katetrizační angiografie a aneuryzmata byla vyplněna kovovými spirálami. Měření bylo provedeno těsně před zavedením mikrokatetru do aneuryzmatu a těsně po něm. Na třírozměrných snímcích byly změřeny rozměry výška-šířka, maximální průměr aneuryzmatu, průměr ústí a angulace. **Výsledky:** Celkem 40 aneuryzmat bylo léčeno endovaskulárním přístupem. V 17 (42,5 %) případech z těchto aneuryzmat nedošlo k ruptuře, ve 23 (57,5 %) případech k ruptuře došlo. Mezi skupinami pacientů s rupturou aneuryzmatu a bez ruptury nebyly statisticky významné rozdíly v demografických údajích a rizikových faktorech, perioperačním měření tlaku ve vaku aneuryzmatu a v mateřské tepně a v morfologických měřeních aneuryzmatu. **Závěr:** V naší studii byla perioperační měření tlaku ve vaku aneuryzmatu a v mateřské tepně podobná jak ve skupině s rupturou aneuryzmatu, tak ve skupině bez ruptury. V žádném z hodnocených parametrů nebyly mezi skupinami pozorovány statisticky významné rozdíly. Mechanizmy hrající roli při vzniku, růstu a ruptuře intrakraniálních aneuryzmat pomohou vysvětlit další studie charakteristik aneuryzmatu, mezi něž patří například jejich tvar nebo vlastnosti stěny.

The authors declare they have no potential conflicts of interest concerning drugs, products, or services used in the study.

Autoři deklarují, že v souvislosti s předmětem studie nemají žádné komerční zájmy.

The Editorial Board declares that the manuscript met the ICMJE "uniform requirements" for biomedical papers.

Redakční rada potvrzuje, že rukopis práce splnil ICMJE kritéria pro publikace zasílané do biomedicínských časopisů.

Key words

pressure measurements – aneurysm sac – aneurysm rupture – arterial hypertension – parent artery

Klíčová slova

měření tlaku – vak aneuryzmatu – ruptura aneuryzmatu – arteriální hypertenze – mateřská tepna

Introduction

Intracranial aneurysms are cerebrovascular lesions with high mortality and morbidity. Various studies show that 3–6% of the population over 30 years of age have an aneurysm. Subarachnoid haemorrhage (SAH) with aneurysm rupture has a mortality of up to 50%. Many factors such as smoking, alcohol consumption, cocaine use, ethnicity, gender, age, family history and most importantly, arterial hypertension may play a role in the formation of aneurysms. However, the mechanisms about the formation, growth and rupture of intracranial aneurysms are not fully elucidated [1]. Arterial hypertension and haemodynamic stress are accepted as the oldest and most widely accepted factors for aneurysm formation and rupture [2,3]. The flow pattern in the aneurysm is thought to be affected by the geometry of the dilatation, the relationship between the aneurysm and the parent artery, the volume of the aneurysm and the aspect ratio [4,5]. The morphological relationship between the aneurysm and the parent artery is important because of its effect on the aneurysmal flow pattern [6]. There are differences in the internal structures and clinical features of ruptured and unruptured aneurysms. Due to this reason, many investigators try to identify the risk factors for intracranial aneurysm rupture. The current risk assessment is based on the size of the aneurysm, and the risk of rupture is higher in large aneurysms [7,8]. However, small aneurysms may also rupture and aneurysm size alone is insufficient to determine the risk of rupture [9]. Therefore, attempts are being made to explain the risk of rupture with more complicated geometric measurements; these attempts focus on the size, location and shape

of the aneurysm [10]. In experimental aneurysms, pressure measurements in the parent artery and aneurysm show similarities [11]. This finding highlights the role of hypertension in aneurysm rupture.

Material and methods

A total of 37 patients treated for intracranial aneurysm were included in the study between May and December 2012 in the Interventional Radiology Unit of Dokuz Eylül University Hospital. The patients were evaluated for demographic data and risk factors such as age, gender, smoking, arterial hypertension and familial history of aneurysm. The ages of the patients ranged from 40 to 66 (mean 53) years. Pediatric patients were excluded from the study. 24 patients were smokers, 11 patients had arterial hypertension and 4 patients had a family history of aneurysm. Imaging and measurements with catheter angiography digital subtraction angiography) were performed for 40 aneurysms including 1 for 35 patients, 2 for 1 patient, and 3 for 1 patient. An informed consent form was obtained from the patients before the treatment. Cases with vasospasms due to SAH were excluded from the study. The patient and aneurysm data are given in Tab. 1.

Perioperative pressure measurement

Perioperative pressure measurement was performed just before and after the microcatheter entered into the aneurysm sac during microcatheterization. The measurements were performed while the microcatheter tip was inside the parent artery (at the neck of the aneurysm) and in the aneurysm sac (in the middle of the sac). All pa-

tients cannulated from the radial artery during general anaesthesia and simultaneous radial arterial pressures were recorded.

Morphological measurements of the aneurysm

Three-dimensional (3D) cerebral angiography images were obtained using software and reconstruction systems. The aneurysm height-width (H/W), neck diameter, maximum dome diameter and entrance angle were measured in 3D images (Fig. 1). The image ratio, H/W ratio and aneurysm average volume were calculated using this volumetric measurement system.

Statistical analysis

The data and statistical analysis were evaluated with SPSS 20.0 (IBM, Armonk, NY, USA). The variables are indicated by mean and distributions. The chi-square test and Fisher's exact test were used for the values specified by counting in statistical analysis. For measured values, correlation analysis and the Wilcoxon test were used for intra-group comparison and the Mann-Whitney U test was used for comparison between groups. Receiver operating characteristic (ROC) analysis was used to evaluate sensitivity and specificity in aneurysm morphological measurements. $P < 0.05$ was accepted for statistical significance.

Results

When comparing patient groups with ruptured and unruptured aneurysms, no statistically significant difference was found between the groups in terms of demographic data and risk factors. The patients showed a homogeneous distribution in both groups. Demographic data about the findings and patients are presented in Tab. 1.

No statistically significant difference was found between the ruptured and non-ruptured aneurysm groups in the comparison of perioperative parent artery and aneurysm pressures (Tab. 2).

Significant correlation was found between the pressure of the parent artery and aneurysm sac (Tab. 3).

In the ruptured and unruptured aneurysm groups, there was no significant difference in the systolic and diastolic pressure values between the parent artery and aneurysm sac, measured simultaneously (Tab. 4).

There were differences between the ruptured and unruptured aneurysms in terms of internal structures and clinical features.

Tab. 1. Descriptive data.

	Ruptured aneurysms (N = 23)	Unruptured aneurysms (N = 17)	P value
age	50.8 ± 11.7	53.2 ± 13.8	0.551
male/female ratio	12 (52.2%) / 11 (47.8%)	10 (71.4%) / 4 (28.6%)	0.247
smoking	16 (69.6%)	8 (57.1%)	0.495
arterial hypertension	7 (30.4%)	4 (28.6%)	1.000
family aneurysm history	2 (8.7%)	2 (14.3%)	0.625
aneurysm location			
• lateral wall	15 (57.7%)	11 (42.3%)	0.487
• bifurcation	8 (57.1%)	6 (42.9%)	

N – number

However, there was no statistically significant difference between the groups in the aneurysm morphological measurements. In addition, no significant difference was found between morphological differences according to rupture status. The morphological data are shown in Tab. 5 and 6.

According to the ROC analysis, the areas under the curve are 0.495 ± 0.097 for the aspect ratio; 0.447 ± 0.094 for the maximum dome diameter (D_{max}); 0.454 ± 0.095 for the inflow angle; 0.425 ± 0.095 for the H/W ratio; and there was no statistical significance ($P > 0.05$).

Discussion

The most widely accepted reasons for aneurysm formation and rupture are arterial hypertension and haemodynamic stress [2,3,12]. Factors such as transmural pressure changes and wall shear stress in the aneurysm and parent artery can be determinant for an aneurysm rupture. These variables may also be affected by the morphology and flow velocity of the parent artery and aneurysm. The flow pattern in the aneurysm is thought to be associated with the shape of the dilatation, the relationship between the aneurysm and the parent artery, the volume of the aneurysm and the aspect ratio. A large aspect ratio is an indicator of intra-aneurysmal stagnation and may be the cause of SAH. In addition, turbulence due to atypical shape of the vessel wall may also cause stress in the aneurysm wall and transmural pressure increase [4,5].

Tab. 3. Evaluation of the relationship between aneurysm sac and parent artery pressures.

	Intra-aneurysmal systolic pressure	Intra-aneurysmal diastolic pressure	Intra-aneurysmal mean pressure
systolic pressure of parent artery	$r = 0.766$	$r = 0.501$	$r = 0.602$
diastolic pressure of parent artery	$r = 0.459$	$r = 0.578$	$r = 0.515$
mean pressure of parent artery	$r = 0.542$	$r = 0.574$	$r = 0.579$

Tab. 4. Comparison of pressures in ruptured and unruptured aneurysms.

	Ruptured aneurysms	Unruptured aneurysms
systolic pressure of parent artery and aneurysm sac	$P = 0.808$	$P = 0.701$
diastolic pressure of parent artery and aneurysm sac	$P = 0.784$	$P = 0.814$
mean pressure of parent artery and aneurysm sac	$P = 0.808$	$P = 0.424$

Tab. 5. Evaluation of rupture status according to the morphological characteristics of the aneurysm.

	Ruptured aneurysms (N = 23)	Unruptured aneurysms (N = 17)	P value
aneurysm neck diameter (mm)	4.47 ± 1.68	4.74 ± 1.73	0.620
aneurysm height (mm)	7.59 ± 4.66	7.58 ± 3.36	0.571
aneurysm width (mm)	7.77 ± 4.46	7.42 ± 3.10	1.000
maximal dome diameter (D_{\max})	8.92 ± 4.56	9.09 ± 3.95	0.571
aneurysm volume (ml)	0.30 ± 0.60	0.31 ± 0.48	0.479
aneurysm aspect ratio	1.79 ± 1.02	1.66 ± 0.63	0.955
aneurysm height/width ratio	0.98 ± 0.20	1.02 ± 0.21	0.428
aneurysm inflow angle	103.77 ± 26.13	108.23 ± 27.55	0.620

N – number

Tab. 6. Evaluation of aneurysm morphological parameters according to rupture status.

	Area under the curve	P value
height/width ratio	0.425 ± 0.095	0.428
inflow angle	0.453 ± 0.095	0.620
aspect ratio	0.495 ± 0.097	0.955
maximal dome diameter (D_{\max})	0.447 ± 0.094	0.571

stress can be determinant in the growth and rupture of aneurysms [13]. The growth of aneurysms depends on the interaction between haemodynamic loads and the mechano-biological responses of cell elements in the wall, resulting in a weakening of the vessel wall [14]. Rupture occurs when the wall stress exceeds the wall

strength of the aneurysm. However, the mechanisms causing growth and rupture have not been fully elucidated. Defining the haemodynamic variables most associated with clinical progression and rupture may help to explain the effects of these mechanisms and improve the treatment approaches.

In a study performed by Sekhar et al [11], experimental models of saccular aneurysms in dogs were created and intra-aneurysmal pressures were measured. Intracarotid and intra-aneurysmal pressures were similar in this study and showed a linear relationship with mean arterial pressure. The results are similar to those in our study, and it is understood that the findings in humans are similar to the experimental aneurysms in animals.

Studies based on intra-aneurysmal and parent artery pressure measurements are limited. In a study conducted by Sorteberg et al [15], no statistical difference in pressure was found in the aneurysm and in the parent artery in the experimental silicone aneurysm models. In another experimental study, aneurysm pressures were similar to those of the parent arterial pressures [16]. The experimental silicon aneurysm models also have similar findings to our results and support the idea that intra-aneurysm pressure alone cannot cause rupture.

There are differences between ruptured and unruptured aneurysms in terms of internal structures and clinical features. Therefore, attempts are being made to explain the risk of rupture using complicated geometric measurements. In a study by Hoh et al, the aneurysm aspect ratio and the H/W width ratio were higher in the ruptured aneurysms [17]. In another study, the inflow angle was defined as an independent separator for the rupture. The inflow angle was significantly higher in ruptured aneurysms in comparison with unruptured aneurysms. Also in this study, D_{\max} , H/W ratio and aspect ratio were significantly higher in ruptured aneurysms. The inflow angle and H/W ratio were defined as an independent and significant separator for the rupture [6]. In another study, however, D_{\max} , aspect ratio and H/W ratio were high in ruptured aneurysms. But only the inflow angle and H/W ratio were found as independent separators and stated as more important than the size of the aneurysm and more reliable in the risk classification of aneurysm morphological features [18]. In our study, the inflow angle, H/W ratio, aneurysm neck diameter and D_{\max} were higher in ruptured aneurysms in comparison with unruptured aneurysms, but these differences were not statistically significant. A study with more cases may change the statistical significance.

As a result of many studies and our study, differences in pressure measurements alone

cannot explain aneurysm rupture and we understand from the results of our study that pressure measurements cannot be used as a treatment planning indicator and cannot guide the treatment algorithm even if done before treatment. On the other hand, pressure measurement is not a practical method because it is performed using catheter angiography, which is an interventional procedure.

Conclusion

In our study, no significant pressure difference was detected in the aneurysm sac and parent artery between unruptured and ruptured aneurysms, and we think that the rupture can be a process related to the multifactorial effect of all conditions that cause stress in an aneurysm, especially the aneurysm shape and vessel wall properties. On the other hand, studies based on intra-aneurysmal and parent artery pressure measurements are limited and we need studies with a wider series based on geometric measurements such as the aneurysm shape and wall properties; this will contribute to our knowledge to better understand the rupture mechanisms.
